

## Compilers

Peephole Optimization

Optimizations can be directly applied to assembly code

- The "peephole" is a short sequence of (usually contiguous) instructions
- The optimizer replaces the sequence with another equivalent one (but faster)

## **Peephole Optimization**

Write peephole optimizations as replacement rules

$$j_1, ..., j_m$$
 where the rhs is the improved version of the lhs

- Example:
  - , move \$a \$b, move \$b \$a  $\rightarrow$ , move \$a \$b,
  - Works if move \$b \$a is not the target of a jump
- Another example
  - addiu \$a \$a i, addiu \$a \$a j  $\rightarrow$  addiu \$a \$a i+j

## **Peephole Optimization**

- Many (but not all) of the basic block optimizations can be cast as peephole optimizations
  - Example: addiu  $$a $b 0 \rightarrow move $a $b$
  - Example: move  $\$a \$a \rightarrow$ \_\_\_\_
  - These two together eliminate addiu \$a \$a 0

 As for local optimizations, peephole optimizations must be applied repeatedly for maximum effect

## **Peephole Optimization**

Many simple optimizations can still be applied on assembly language

- "Program optimization" is grossly misnamed
  - Code produced by "optimizers" is not optimal in any reasonable sense
  - "Program improvement" is a more appropriate term
